RESEARCH MEMORANDUMWIND-TUNNEL INVESTIGATION AT MACH NUMBERS FROM 0.6 TO  
1.4 OF SEVERAL EJECTED PILOT-SEAT MODELS

By James L. Summers

## SUMMARY

The results are presented of an experimental investigation conducted to determine the static longitudinal and lateral-directional aerodynamic characteristics of basic and modified versions of a conventional upward ejected pilot-seat combination, a sled-type upward ejected pilot-seat combination, and a downward ejected pilot-seat combination. Modifications to the basic models incorporated flow deflectors for pilot protection and drag reduction and various stabilizing devices. Test Mach numbers varied from 0.6 to 1.4, angles of attack from  $-28^\circ$  to  $+40^\circ$ , and angles of side-slip from  $-16^\circ$  to  $+12^\circ$ . Reynolds numbers ranged from 0.9 million to 1.8 million based on the projected frontal height of the models.

Analysis of the results indicates that longitudinal and directional stability with possibly marginal dihedral effect can be achieved with the aid of stabilizing devices at the trim angles of attack over the Mach number range of the investigation. The results also indicate that flow deflectors can be employed to reduce the drag.

## INTRODUCTION

The problem of safe pilot escape from aircraft is made difficult by high operational speeds. Conventional pilot-seat combinations are subjected to large decelerations because of their high drag when they are ejected at transonic and higher speeds. Further, loads would be imposed on the pilot's extremities as a result of the more or less violent tumbling motions of an unstabilized seat and also on portions of his body as a result of air blast. An investigation has been conducted in the Ames 2- by 2-foot transonic wind tunnel of models of three basic pilot-seat combinations considered representative of existing or proposed upward and downward ejected escape combinations. Modifications to the basic models consisted of the addition of flow deflectors and various stabilizing devices. The purpose of this report is to present the static longitudinal and lateral-directional aerodynamic characteristics of the several escape

combinations investigated. Test Mach numbers varied from 0.6 to 1.4, angles of attack from  $-28^\circ$  to  $+40^\circ$ , and angles of sideslip from  $-16^\circ$  to  $+12^\circ$ . Reynolds numbers ranged from 0.9 million to 1.8 million, based on the projected frontal height of the models.

#### NOTATION

##### Data

All force and moment coefficients are referred to the stability axis system.

$C_D$	drag coefficient
$C_L$	lift coefficient
$C_l$	rolling-moment coefficient
$C_m$	pitching-moment coefficient
$C_n$	yawing-moment coefficient
$C_Y$	side-force coefficient
M	Mach number
R	Reynolds number
$\alpha$	angle of attack, deg
$\beta$	angle of sideslip, deg

#### Model Symbols

B	boom
D	flow deflector
F	fin
H	horizontal surface
$S_1$	conventional upward ejected pilot-seat combination
$S_2$	sled-type upward ejected pilot-seat combination
$S_3$	downward ejected pilot-seat combination

V vertical surface

i incidence of horizontal surface of model  $S_1$ , positive when trailing edge is down, deg

$\delta$  deflection of flow deflector of model  $S_1$ , positive when deflector is above horizontal reference line, deg

#### Subscripts

a,b designations identifying shape of bottom of seat of the  $S_1$  combinations

### APPARATUS AND MODELS

The Ames 2- by 2-foot transonic wind tunnel is a closed-circuit, variable-pressure tunnel in which the Mach number can be varied continuously to 1.4. A complete description of the wind tunnel and its air-flow characteristics is provided in reference 1.

Three basic pilot-seat combinations with and without various modifications were investigated. Drawings of the several arrangements are presented in figures 1, 2, and 3, respectively, for the models embodying the conventional upward ejected pilot-seat combination ( $S_1$ ), the sled-type upward ejected pilot-seat combination ( $S_2$ ), and the downward ejected pilot-seat combination ( $S_3$ ). For the  $S_1$  combinations, two variations in the shape of the bottom of the seat were tested and are identified by the subscript a or b (see fig. 1(a)). The basic  $S_{1a}$  or  $S_{1b}$  combination was modified by adding a flow deflector  $D_1$  and horizontal and vertical surfaces  $H_1$  and  $V_1$ , respectively (fig. 1(b)). Variations of the  $S_{1b}$  combination were produced by changing the angle of the flow deflector and the incidence of the horizontal surface. The basic  $S_2$  combination was modified as shown in figures 2(b), 2(c), and 2(d), respectively, by adding booms alone ( $B_1$ ), booms with fins swept  $45^\circ$  ( $B_2F_1$ ), and booms with fins swept  $75^\circ$  ( $B_2F_2$ ), in order to provide stability. No flow deflector was employed on the  $S_2$  combinations. Modifications to the  $S_3$  combination consisted of the additions of a flow deflector  $D_2$ , horizontal surfaces  $H_2$  and  $H_3$ , and vertical surfaces  $V_2$  (figs. 3(b) and 3(c)).

All models were sting supported in the wind-tunnel test section as shown in figure 4 for the  $S_3D_2V_2$  model.

## TESTS AND DATA REDUCTION

Lift, drag, side force, pitching moment, yawing moment, and rolling moment were measured for all models tested. The ranges of angles of attack and sideslip varied for each model investigated; however, the test limits were  $-28^\circ$  and  $+40^\circ$  for angle of attack and  $-16^\circ$  and  $+12^\circ$  for angle of sideslip. The test Reynolds numbers and Mach numbers for the various models are presented in figure 5. At some Mach numbers a variation in Reynolds number occurred and the upper and lower limits are indicated in figure 5.

All force and moment coefficients were based on the projected frontal areas of the basic models and the reference length for the moment coefficients was the projected frontal heights of the basic models. The model dimensions employed are as follows:

<u>Combination</u>	<u>Reference area, sq. in.</u>	<u>Reference length, in.</u>
$S_1$	8.42	4.62
$S_2$	6.07	3.46
$S_3$	8.90	4.85

The reference point for the moment coefficients was the center of gravity of the basic models as shown in figures 1, 2, and 3 for the  $S_1$ ,  $S_2$ , and  $S_3$  combinations, respectively. The drag coefficient as presented is the total drag coefficient (i.e., no adjustment has been made for the difference between the model base pressure and the free-stream static pressure). Angle of attack was referred to the horizontal reference line for each model. (See figs. 1, 2, and 3.)

Corrections were applied to the angles of attack and sideslip to take into account deflections of the sting support system resulting from static aerodynamic loads. Corrections have not been applied for wall interference, drag buoyancy or air-stream angularity as they are believed to be negligible for the results presented herein.

## RESULTS AND DISCUSSION

### General

The basic six-component data of the subject investigation are presented in tabular form for the several models as follows:

Conventional upward ejected pilot seat		Sled-type upward ejected pilot seat		Downward ejected pilot seat	
Combination	Table	Combination	Table	Combination	Table
$S_{1a}$	I	$S_2$	V	$S_3$	IX
$S_{1a}D_1H_1V_1$	II	$S_2B_1$	VI	$S_3D_2$	X
$S_{1b}$	III	$S_2B_2F_1$	VII	$S_3D_2V_2$	XI
$S_{1b}D_1H_1V_1$	IV	$S_2B_2F_2$	VIII	$S_3D_2H_2E_3V_2$	XII

The data of tables II and IV are divided into groups of various combinations of flow-deflector deflections and horizontal-surface incidences. In addition, the data of tables III through XII are divided into groups of constant Mach number.

It is to be noted that values of side-force, yawing-moment, and rolling-moment coefficient include tabulations for  $0^\circ$  angle of sideslip for all models. The tabulation of these additional values was necessary because of slight asymmetry of certain models with resulting increments in the lateral force and moment coefficients evident at  $0^\circ$  sideslip angle (e.g., see table II).

#### Conventional Upward Ejected Pilot-Seat Combinations

The effects of the alteration to the bottom of the seat on the longitudinal aerodynamic characteristics of either the basic or modified combinations are shown in figure 6 for 0.95 Mach number. It is seen that the removal of the wedge portion of the seat resulted in a decrease in both drag and lift coefficient at the higher angles of attack. This is to be expected since the removal of the wedge section reduces the frontal area normal to the air stream and thus the model drag and also reduces the angle of attack of the bottom surface of the seat thereby reducing the lift. No appreciable change in the pitching-moment characteristics (fig. 6) or the lateral-directional characteristics (compare the data of table I with III and table II with IV) resulted from the alteration to the seat bottom.

An examination of the data for the  $S_{1b}D_1H_1V_1$  combination (table IV) indicates that the primary effect of a change in either the flow-deflector angle or the horizontal-surface incidence angle or both is a change in the angle of attack for trim. When comparisons are made at trim angle of attack, the lowest drag coefficient is exhibited by the combination having a flow-deflector angle of  $-32^\circ$  and an incidence angle of  $-17^\circ$ . Data for this combination were selected for comparison with similar data for the basic  $S_{1b}$  combination in figure 7. At the angle of attack for trim, the modified combination has appreciably greater longitudinal stability

and a more positive lift than does the basic  $S_{1b}$  combination at the same angle of attack with, however, a small increase in drag. Examination of the lateral-directional characteristics at  $28^\circ$  angle of attack (near trim angle of attack) presented in figure 7(b) indicates the modified combination to have substantial directional stability and small adverse dihedral effect.

#### Sled-Type Upward Ejected Pilot-Seat Combinations

The effects of adding extensible booms to the sled-type basic  $S_2$  combination are shown in figure 8. At trim angle of attack, substantial longitudinal stability and lift with a small increase in drag are developed by the modified combination at the three test Mach numbers. The directional stability of the basic combination is substantially increased by the addition of the booms although the modified combination is slightly unstable at sideslip angles less than  $4^\circ$  at 0.60 Mach number (fig. 8(b)). It is observed that positive dihedral effect is provided throughout the Mach number range by both the basic and modified combinations.

The basic  $S_2$  combination was also tested with somewhat shorter booms equipped with fins ( $S_2B_2F_1$  and  $S_2B_2F_2$ ). An examination of the tabular data (tables VII and VIII) indicates that the boom-fin arrangements provided longitudinal stability but with a fairly large variation with Mach number of the angle of attack for trim. Directional stability is also provided; however, adverse dihedral effect is apparent for both finned combinations, particularly for the combination having a fin sweepback of  $45^\circ$  ( $S_2B_2F_1$ ).

#### Downward Ejected Pilot-Seat Combinations

The basic  $S_3$  combination was modified by the addition, in order, of the flow deflector  $D_2$ , the vertical surface  $V_2$ , and, lastly, the horizontal surfaces  $H_2$  and  $H_3$ . The aerodynamic data for the four combinations are presented in tables IX through XII. An examination of the data contained in tables IX and X to determine the effect of the addition of the flow deflector to the basic seat combination indicates that at angles of attack near  $0^\circ$ , the flow deflector provided a substantial decrease in drag for the basic seat. This is illustrated in figure 9 where the variations with Mach number of the drag coefficients of the  $S_3$  and  $S_3D_2$  combinations are compared for  $0^\circ$  angle of attack. At 1.40 Mach number, the drag of the  $S_3D_2$  combination is seen to be about 31 percent less than that of the basic  $S_3$  combination.

A comparison of the aerodynamic characteristics of the basic  $S_3$  combination with those of the modified combination  $S_3D_2H_2H_3V_2$  is presented in figure 10. It is noted that the modified configuration provides

longitudinal stability at trim angle of attack at 0.60 and 1.00 Mach number but not at 1.40 Mach number. In fact, at 1.40 Mach number the modified model falls just short of providing trim in the angle range tested. Furthermore, the range of angles of attack for which stability does occur, although out of trim, is small (particularly at 0.60 Mach number) in comparison to the previously discussed modified  $S_1$  and  $S_2$  combinations. Since the  $S_1$  and  $S_3$  combinations are basically similar, it seems reasonable to believe that a horizontal surface similar to that employed on the  $S_1$  combination could provide longitudinal stability for the  $S_3$  combination. It is observed that at or near its trim angle of attack, the  $S_3D_2H_2H_3V_2$  combination provided an increase in lift and a small decrease in drag compared to the basic  $S_3$  combination. The decrease in drag is attributed to the favorable effect of the flow deflector.

An examination of the lateral-directional characteristics in figure 10(b) indicates the  $S_3D_2H_2H_3V_2$  combination to have some directional stability at  $0^\circ$  sideslip angle but also to have adverse dihedral effect for the three test Mach numbers.

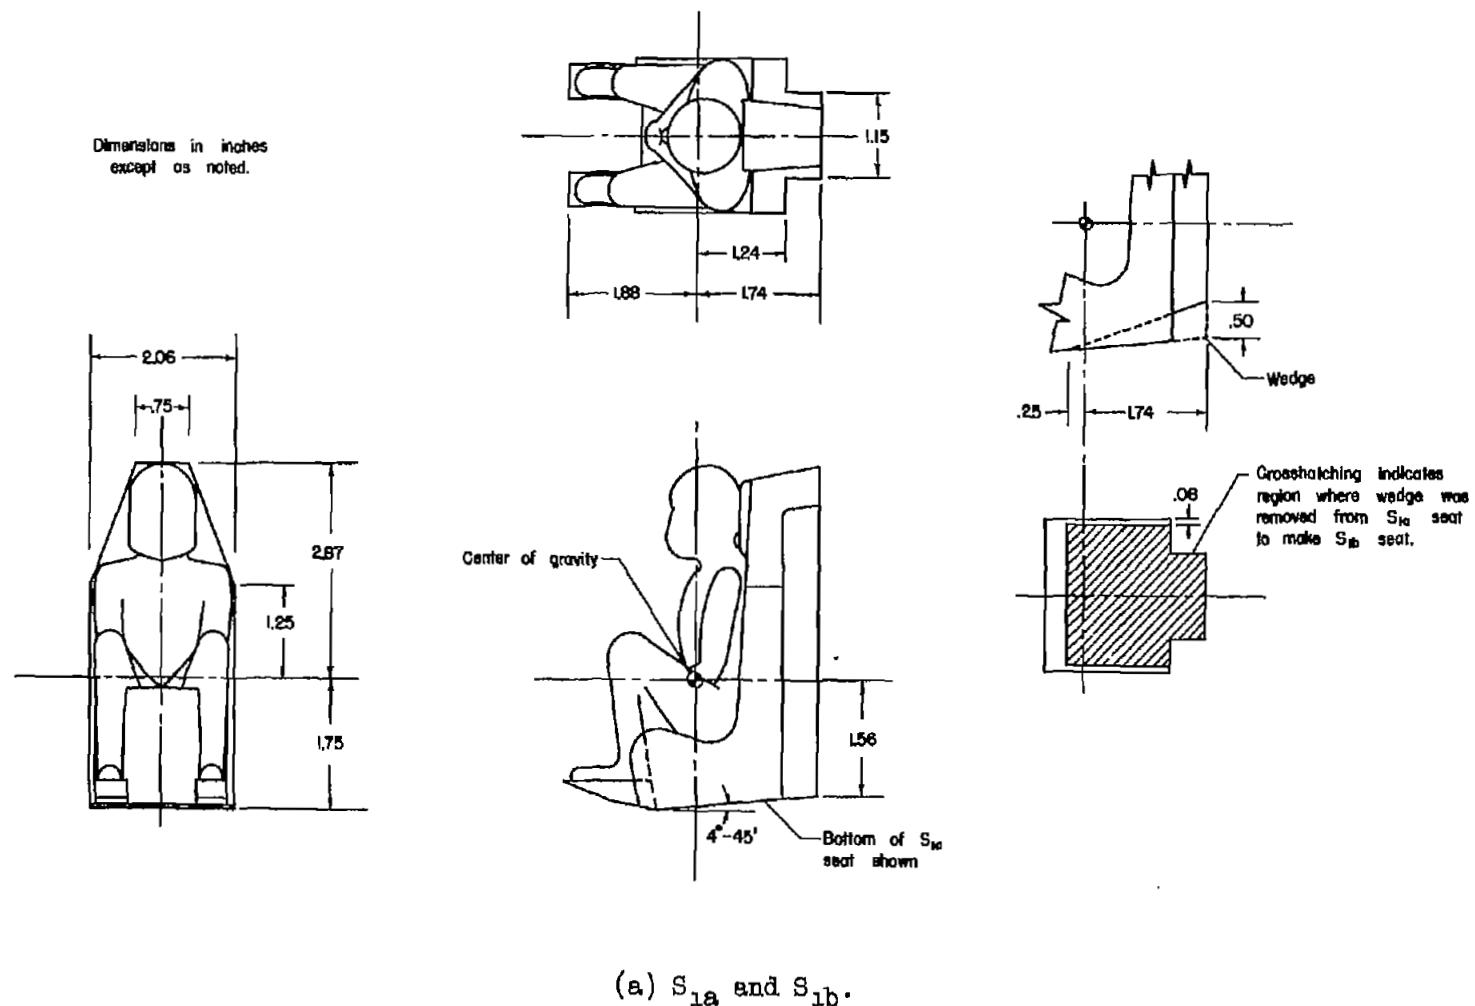

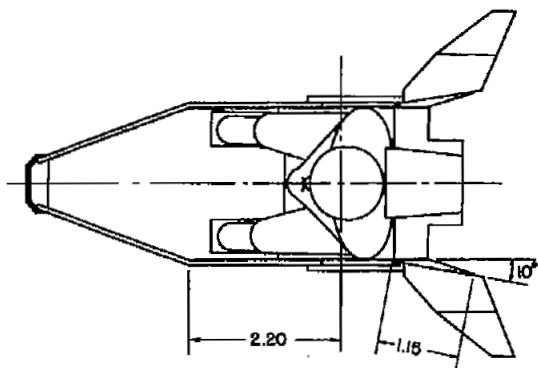

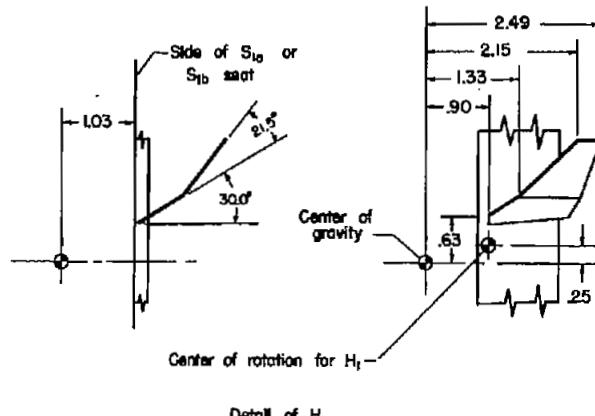

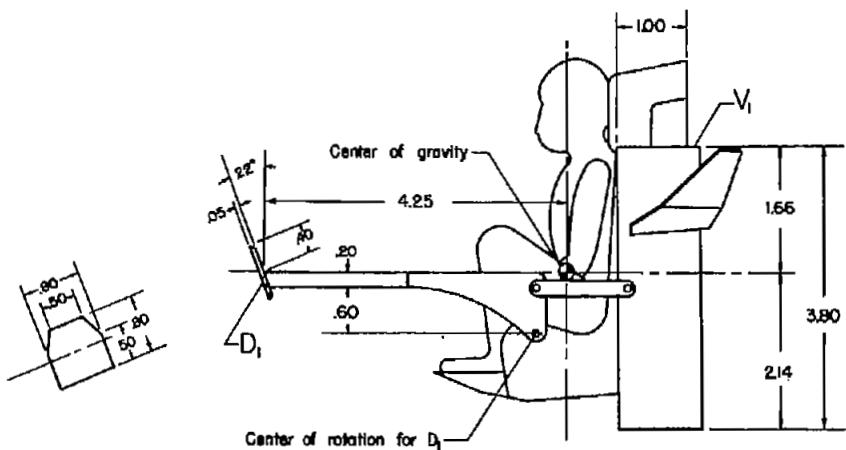

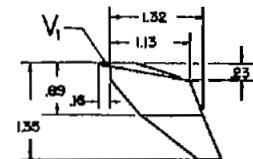

Figure 1.- Models employing the conventional upward ejected pilot-seat combination.

Dimensions in inches  
except as noted.

(b)  $S_{1a}D_1H_1V_1$ ,  $\delta = 0^\circ$ ,  $i = 0^\circ$

Figure 1.- Concluded.

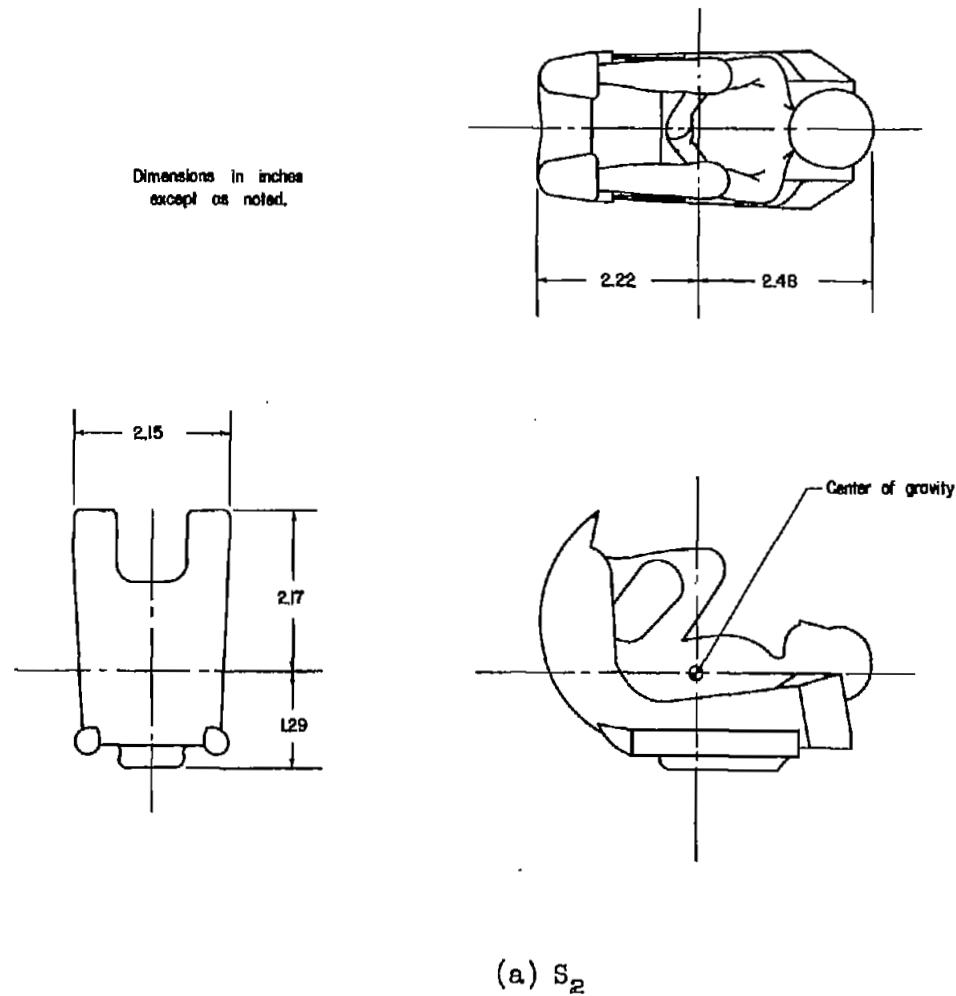

Figure 2.- Models employing the sled-type upward ejected pilot-seat combination.

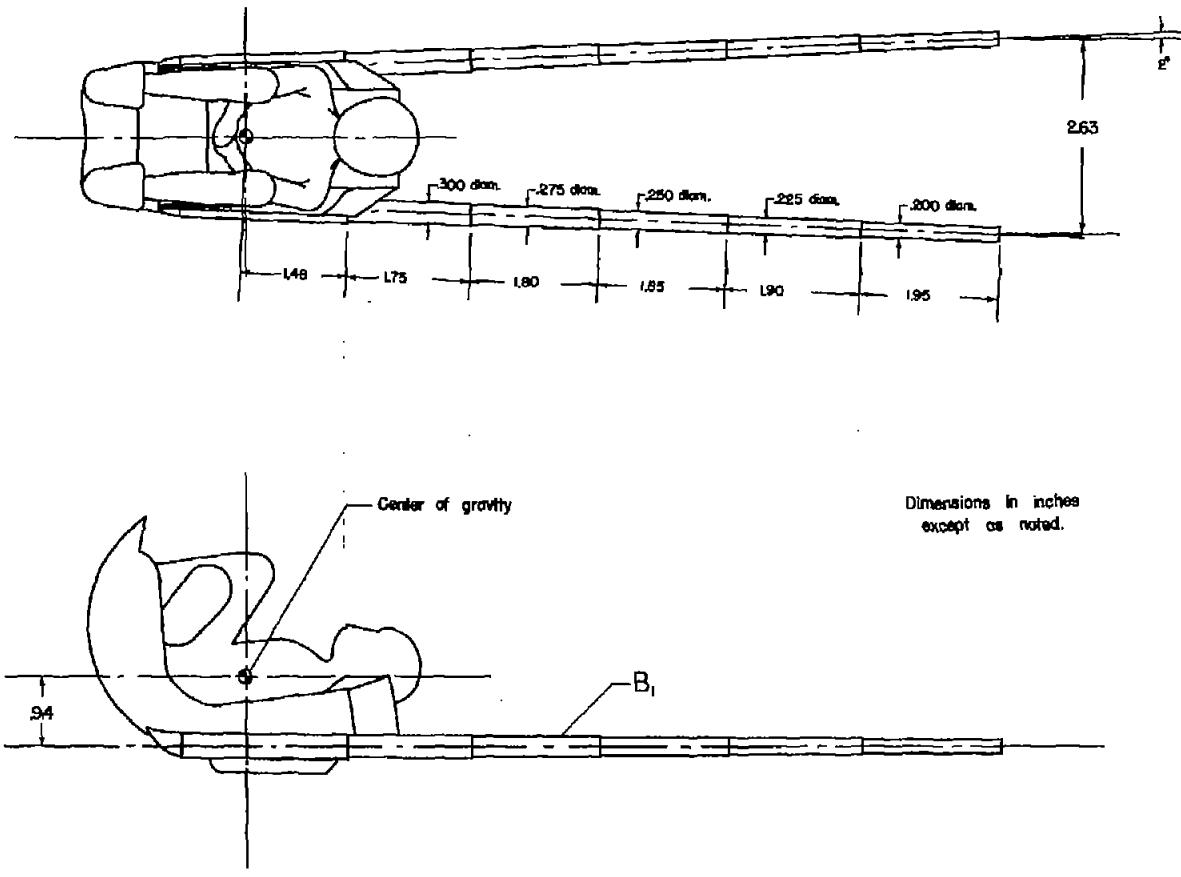

(b)  $S_2 B_1$ 

Figure 2.- Continued.

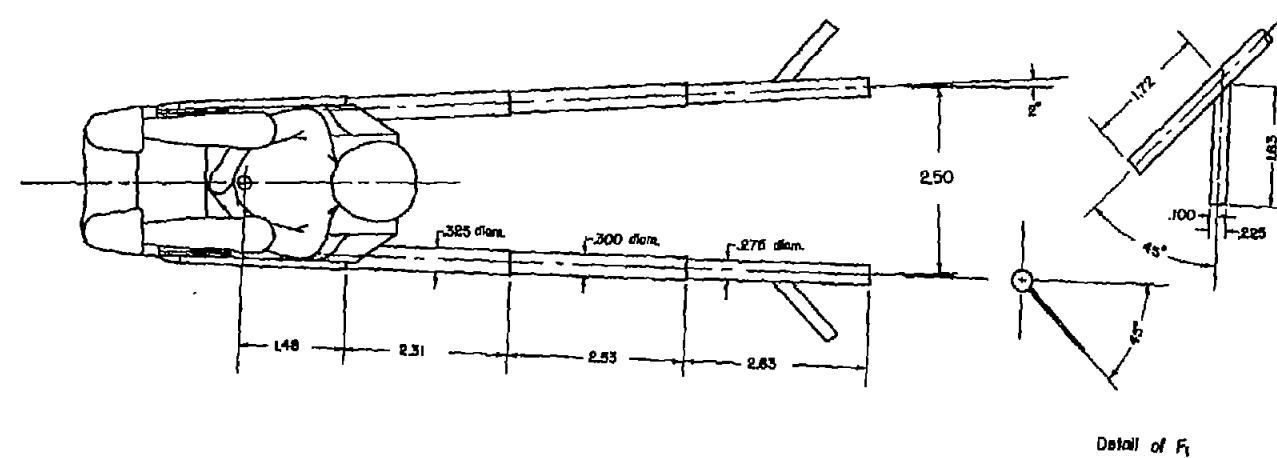

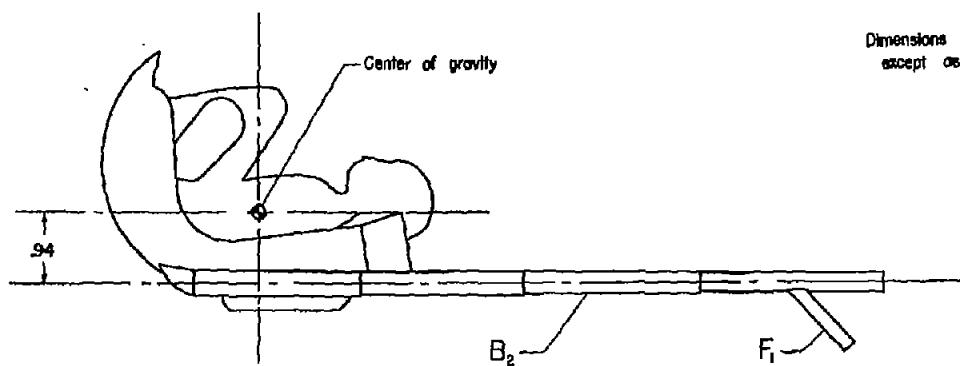

Detail of  $F_1$ (c)  $S_2 B_2 F_1$ 

Figure 2.- Continued.

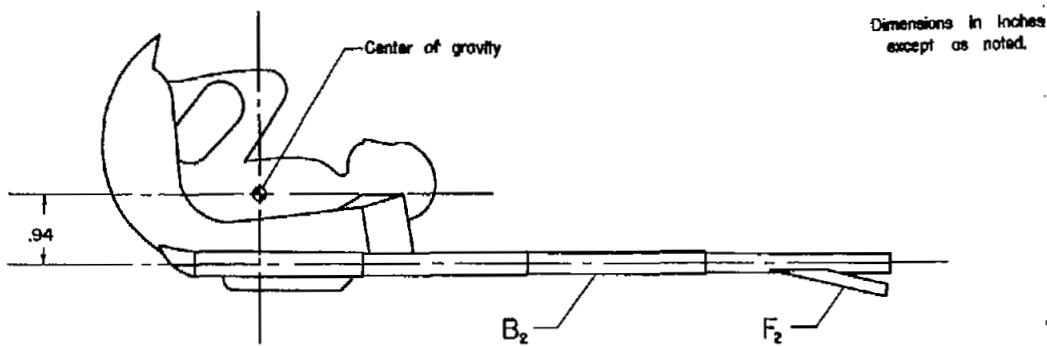

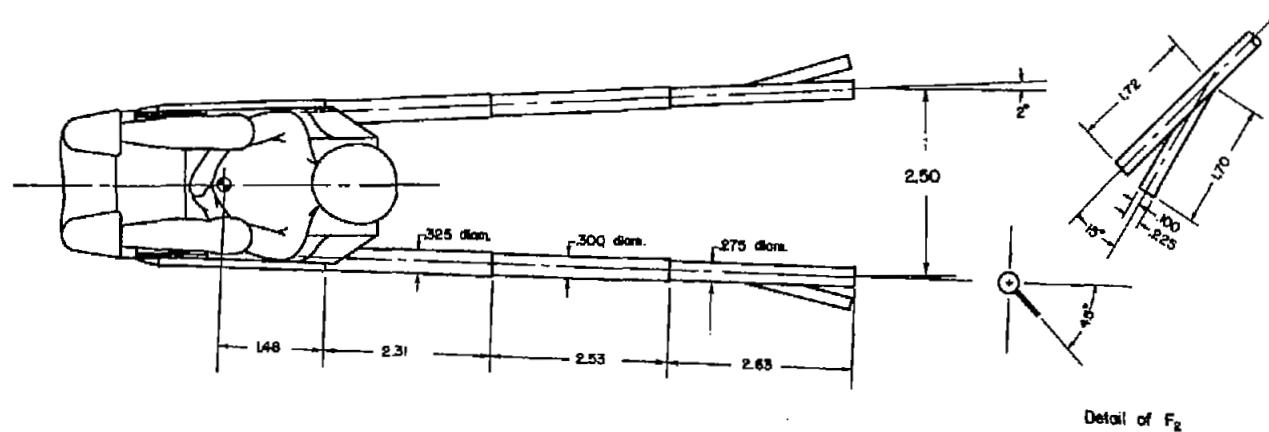

(d)  $S_2B_2F_2$ 

Figure 2.- Concluded.

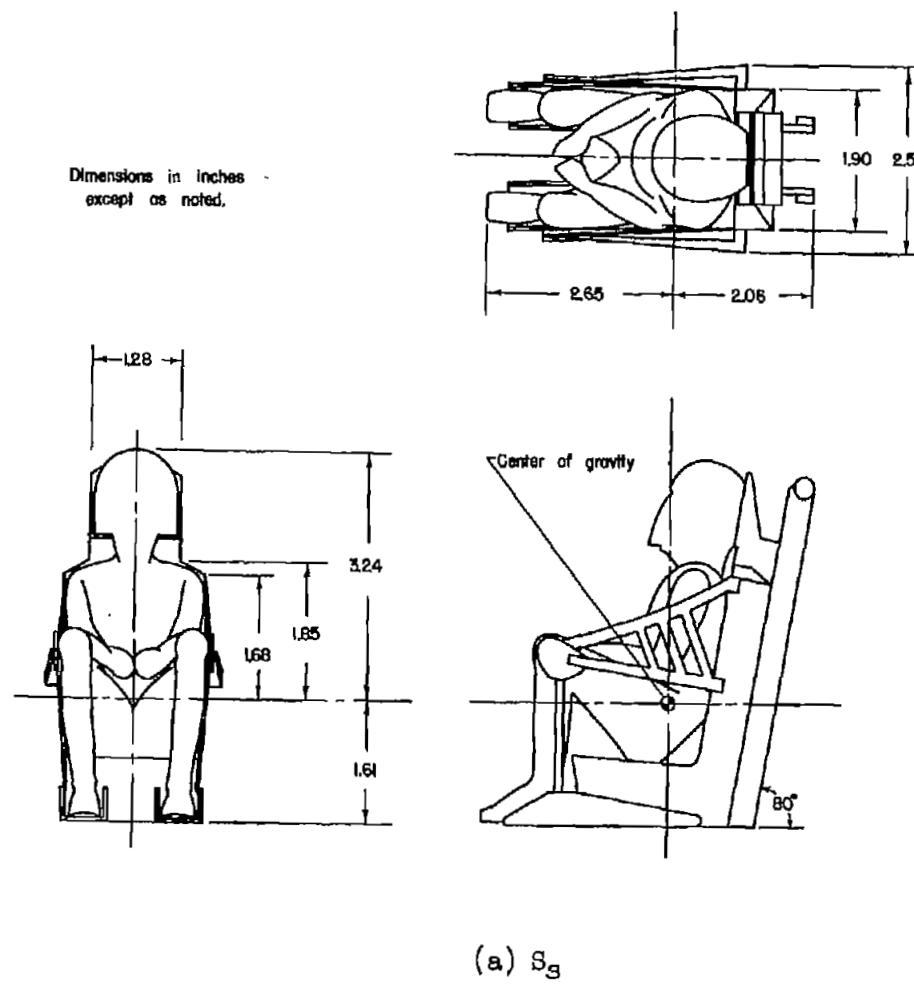

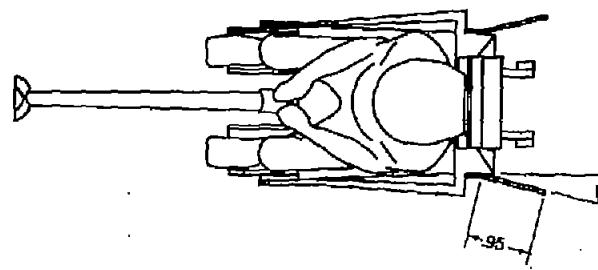

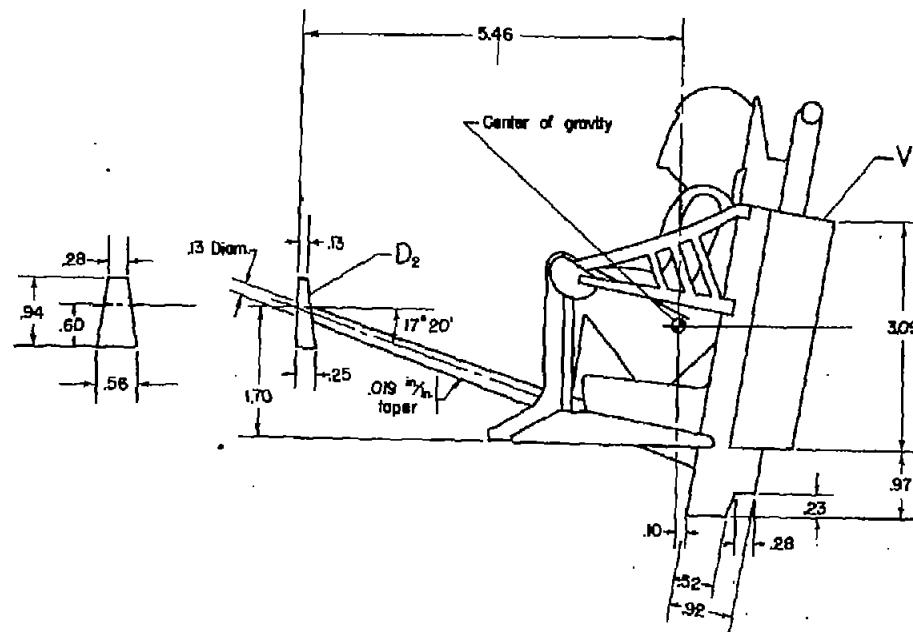

Figure 3.- Models employing the downward ejected pilot-seat combination.

Dimensions in Inches  
except as noted.

(b)  $S_3D_2V_2$

Figure 3.- Continued.

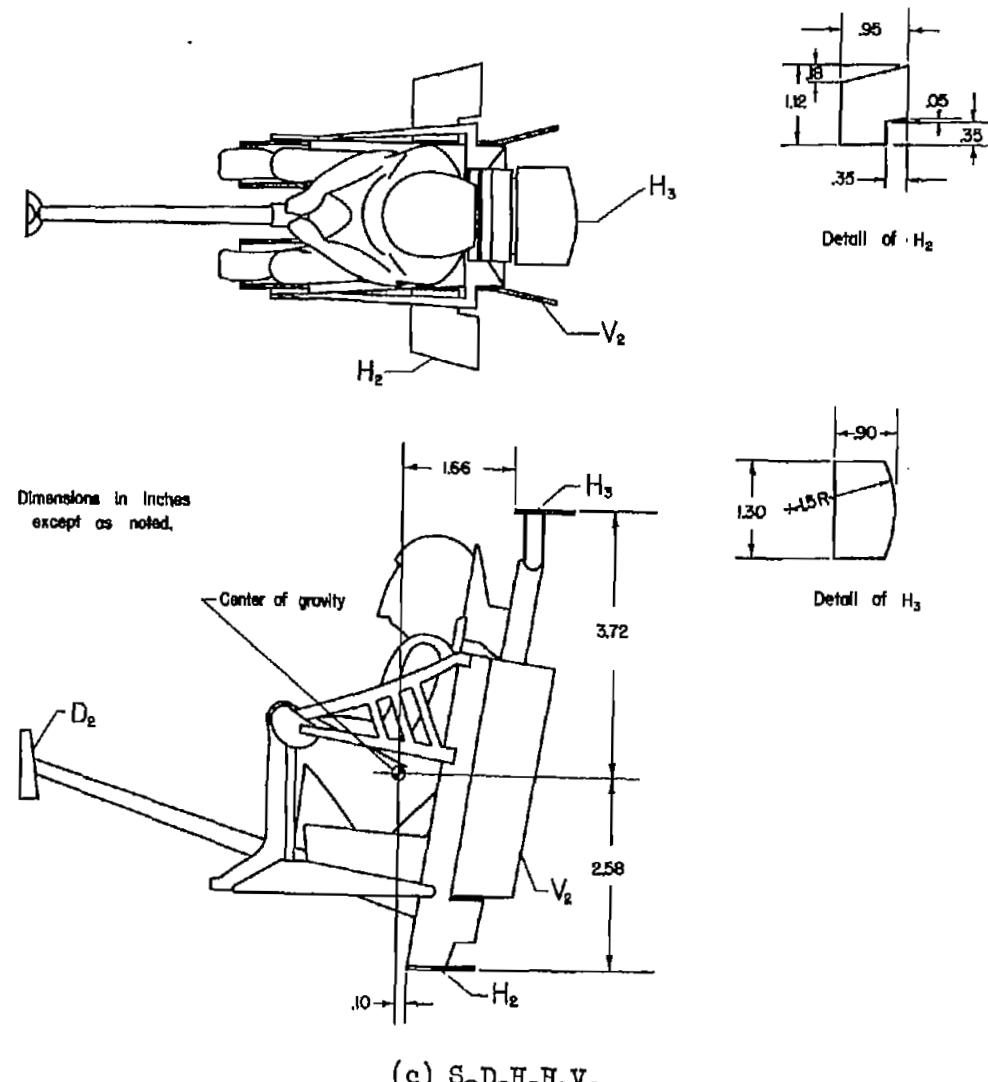

Figure 3.- Concluded.

A-21348

Figure 4.- The downward ejected pilot-seat combination installed in the Ames 2- by 2-foot transonic wind tunnel.

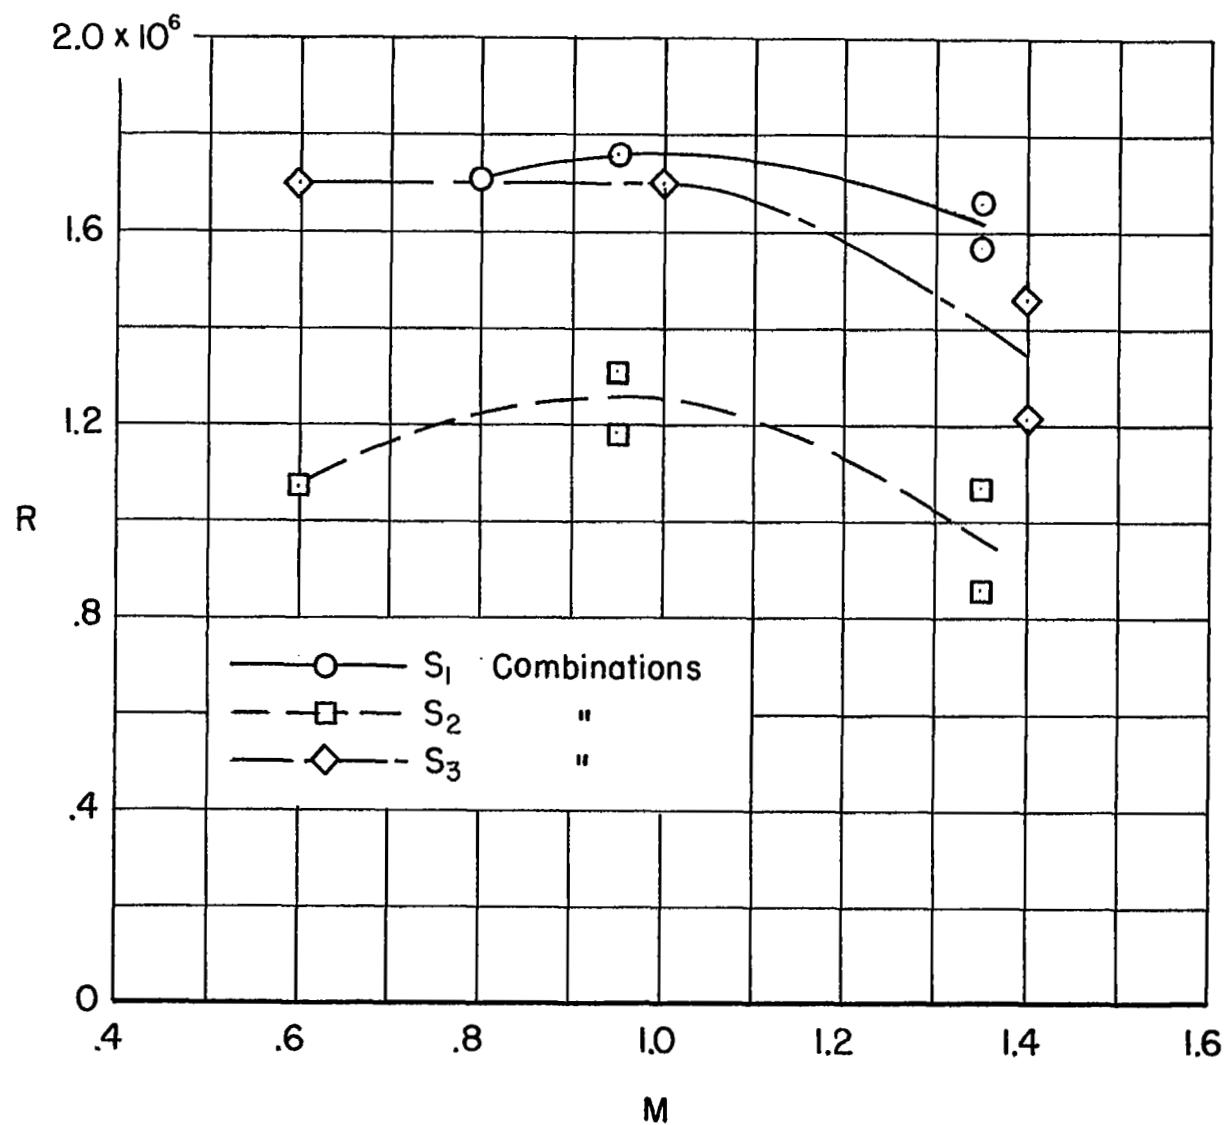

Figure 5.- Test Reynolds numbers and Mach numbers.

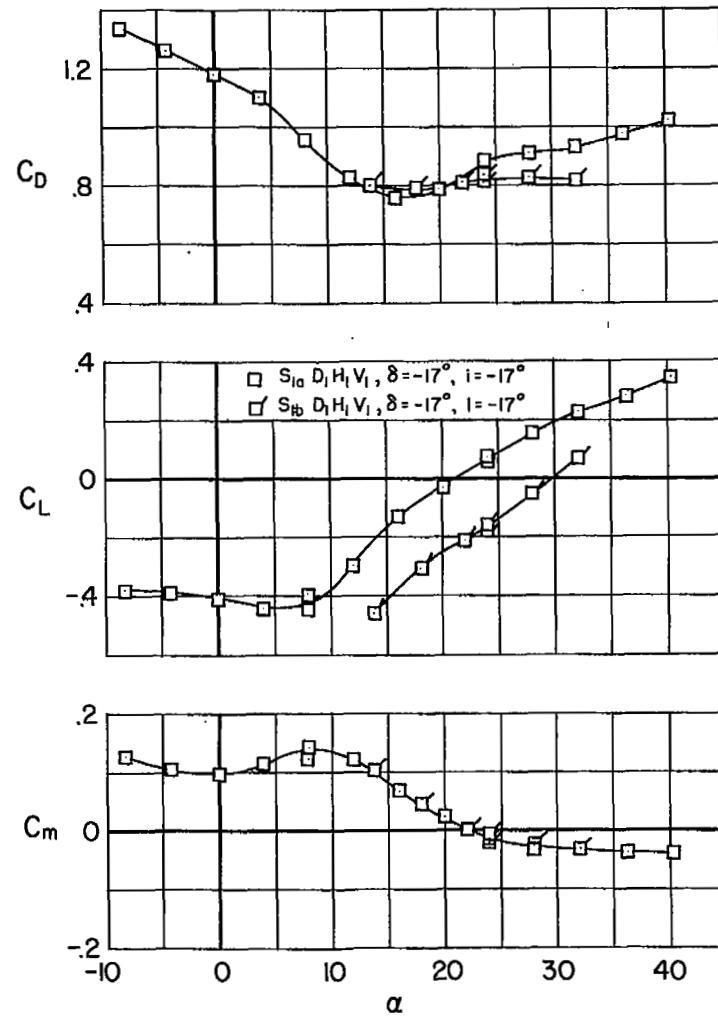

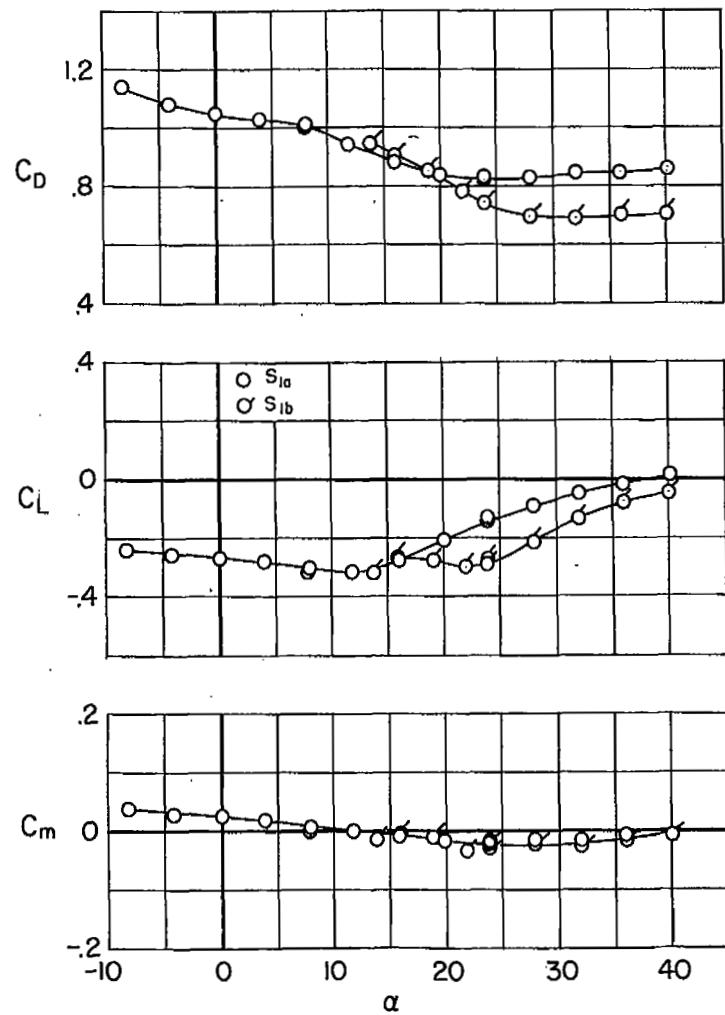

Figure 6.- Effect of variation in seat shape on the longitudinal aerodynamic characteristics of the basic and modified conventional upward ejected pilot-seat combinations;  $M = 0.95$ .

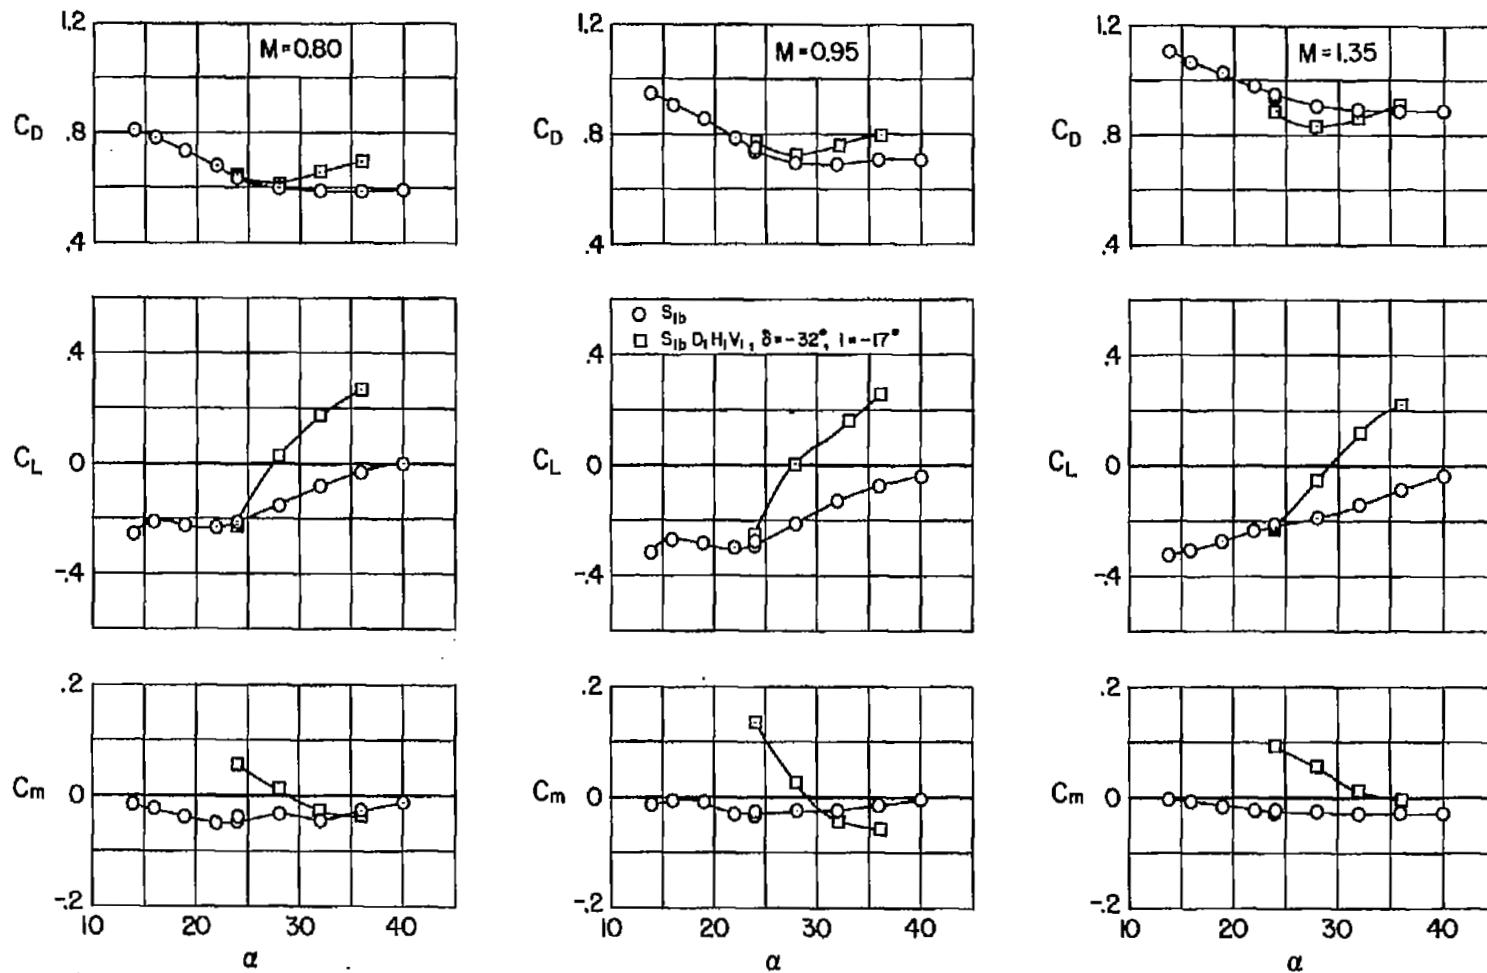

(a) Longitudinal characteristics at  $\beta = 0^\circ$ .

Figure 7.- Aerodynamic characteristics of the basic and modified conventional upward ejected pilot-seat combinations.

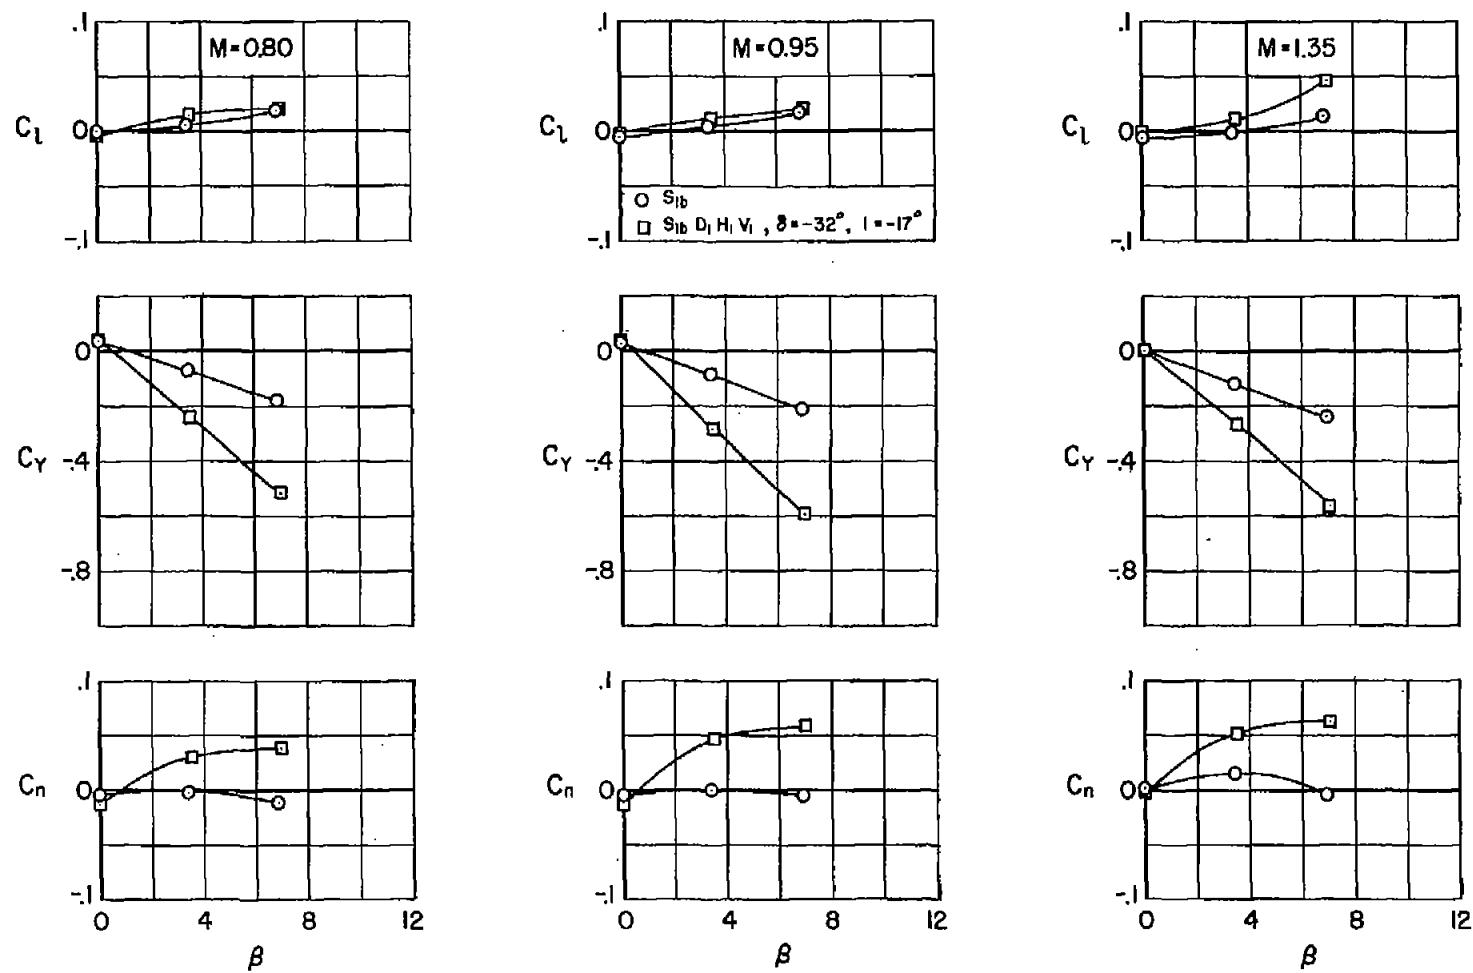

(b) Lateral-directional characteristics at  $\alpha = 28^\circ$ .

Figure 7.- Concluded.

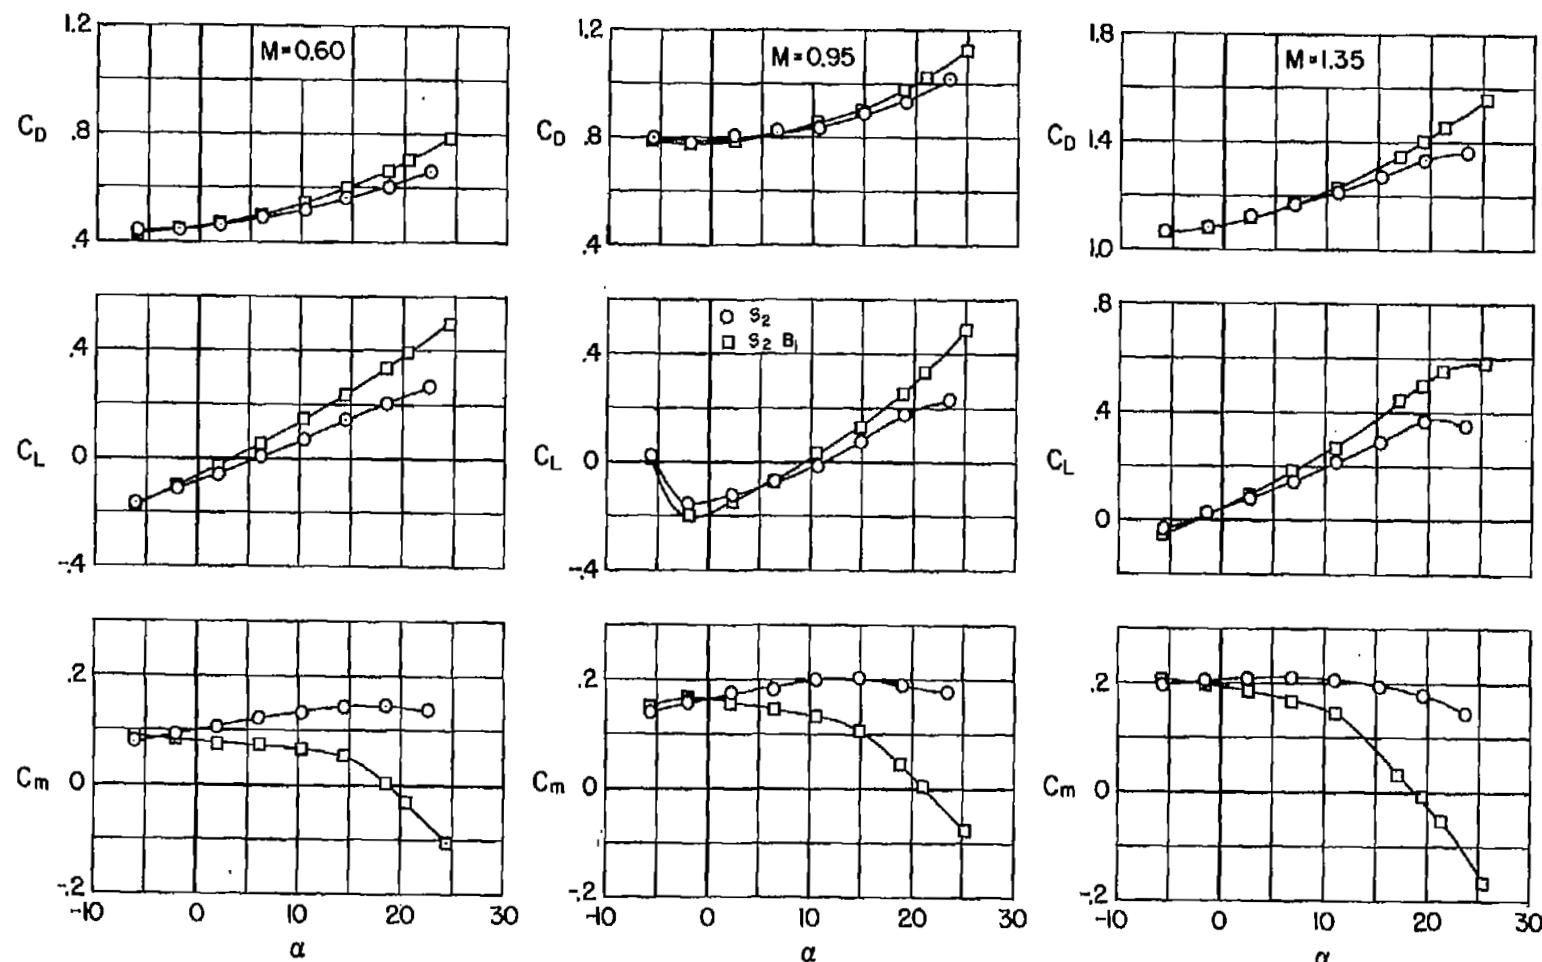

(a) Longitudinal characteristics at  $\beta = 0^\circ$ .

Figure 8. - Aerodynamic characteristics of the basic and modified sled-type upward ejected pilot-seat combinations.

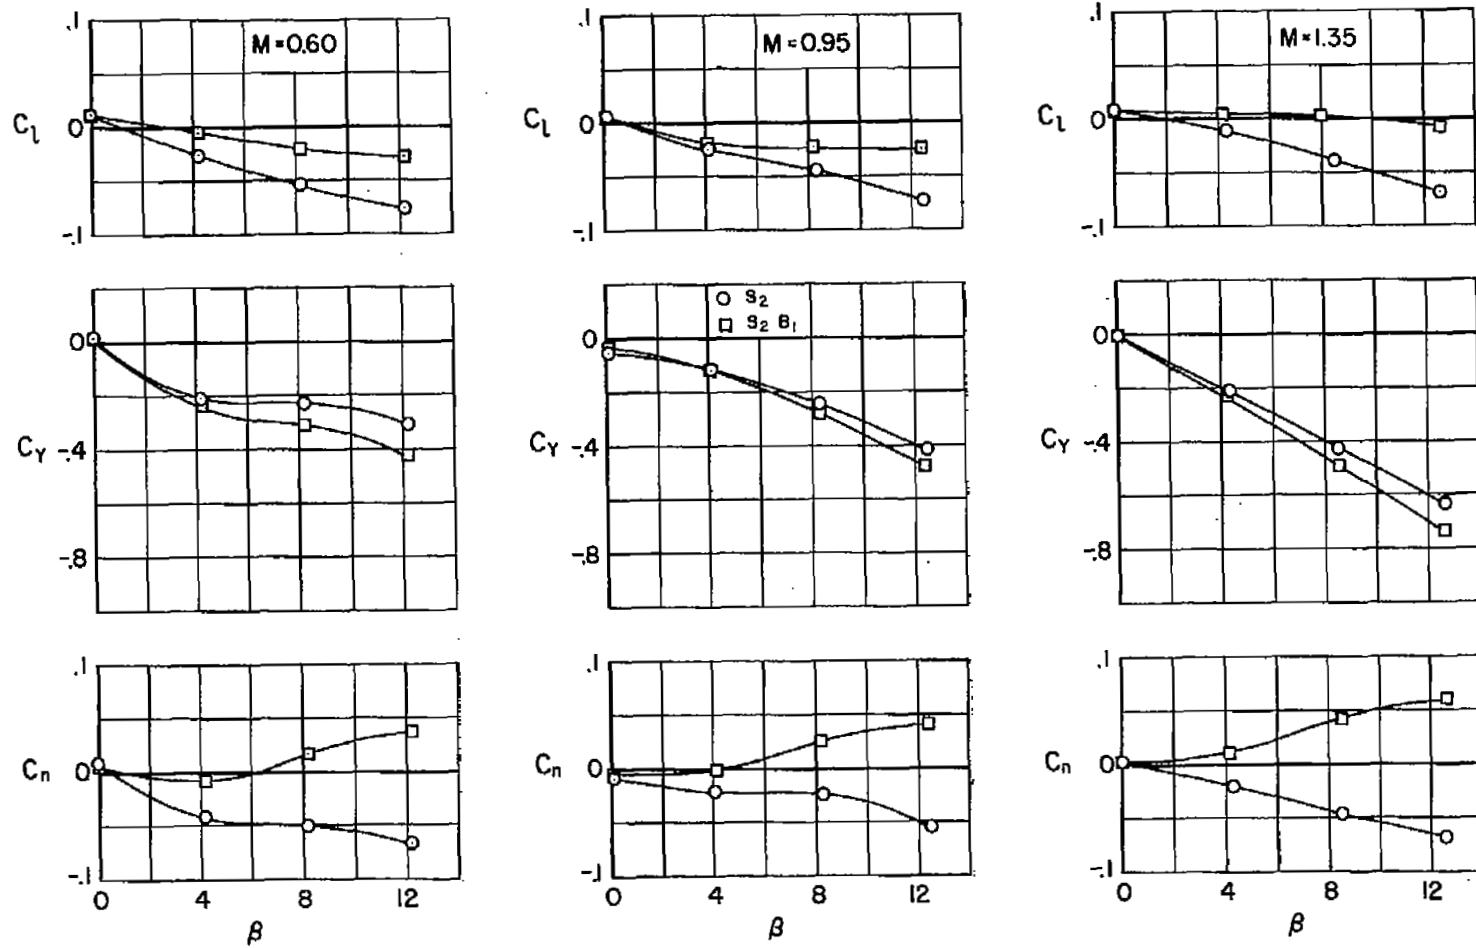

(b) Lateral-directional characteristics at  $\alpha = 19^\circ$ .

Figure 8.- Concluded.

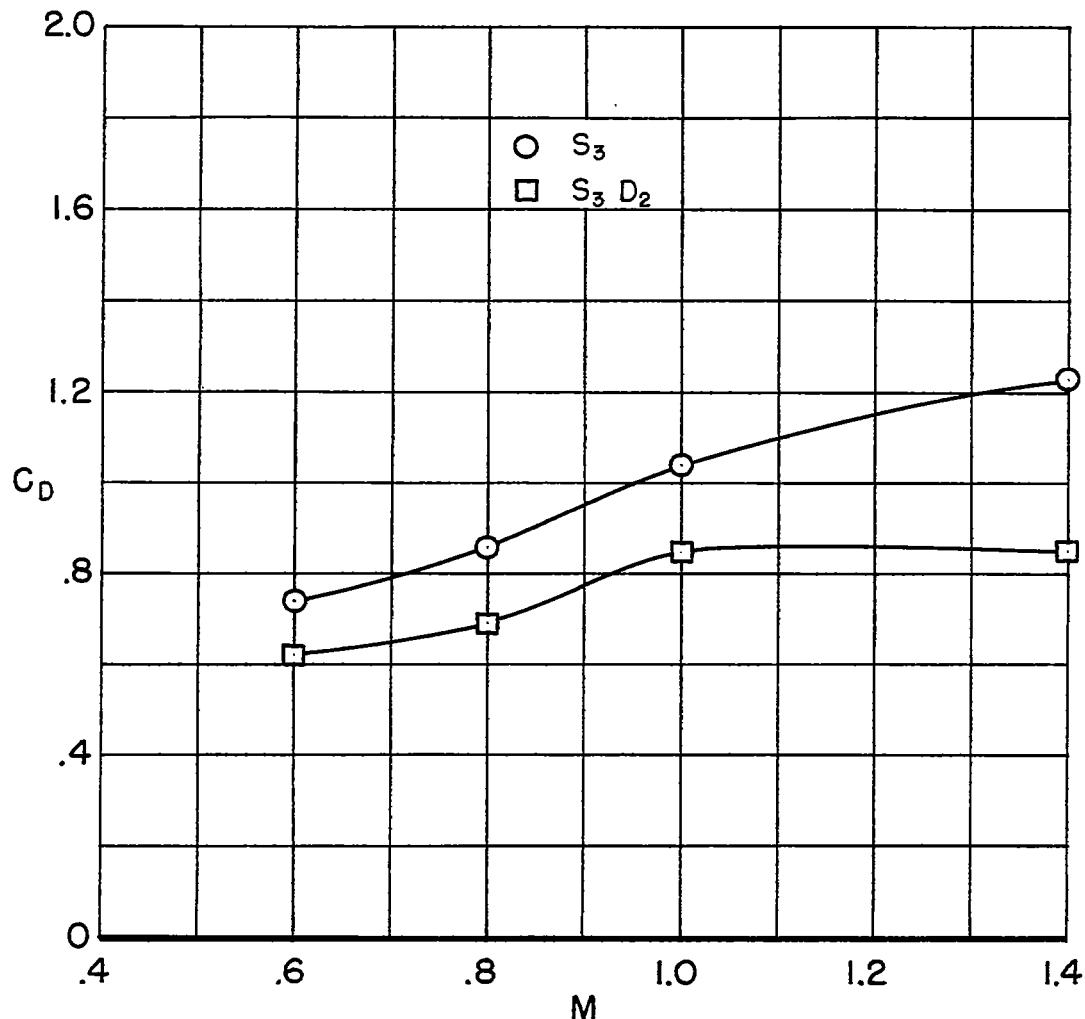

Figure 9.- Variation with Mach number of the drag coefficient of the downward ejected pilot-seat combination with and without flow deflector;  $\alpha = 0^\circ$ .

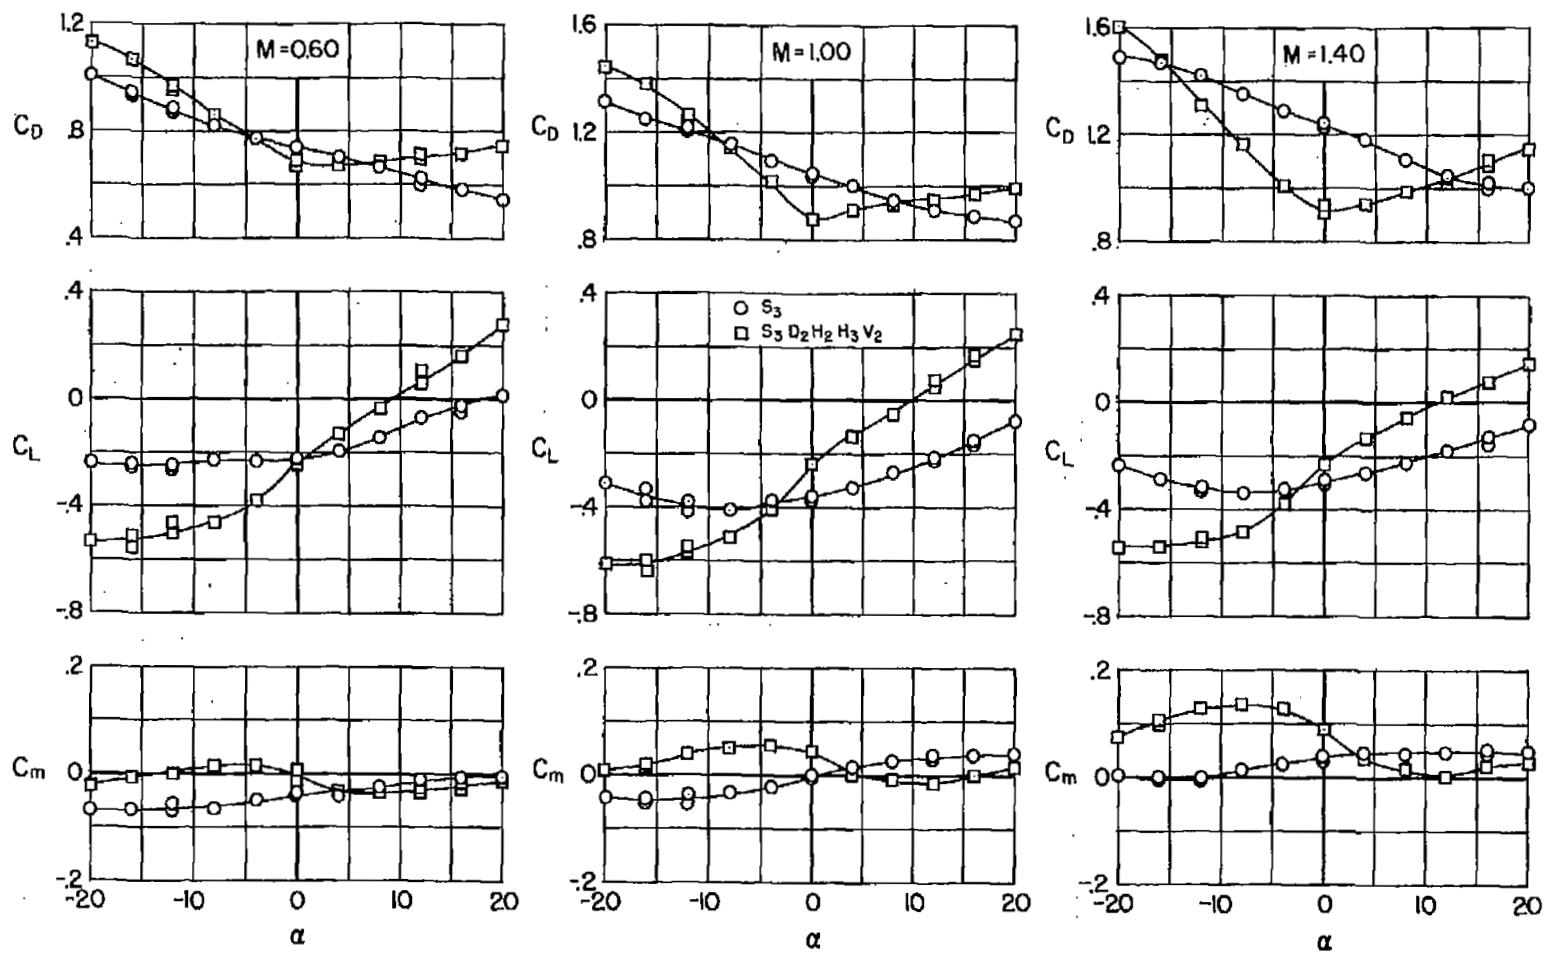

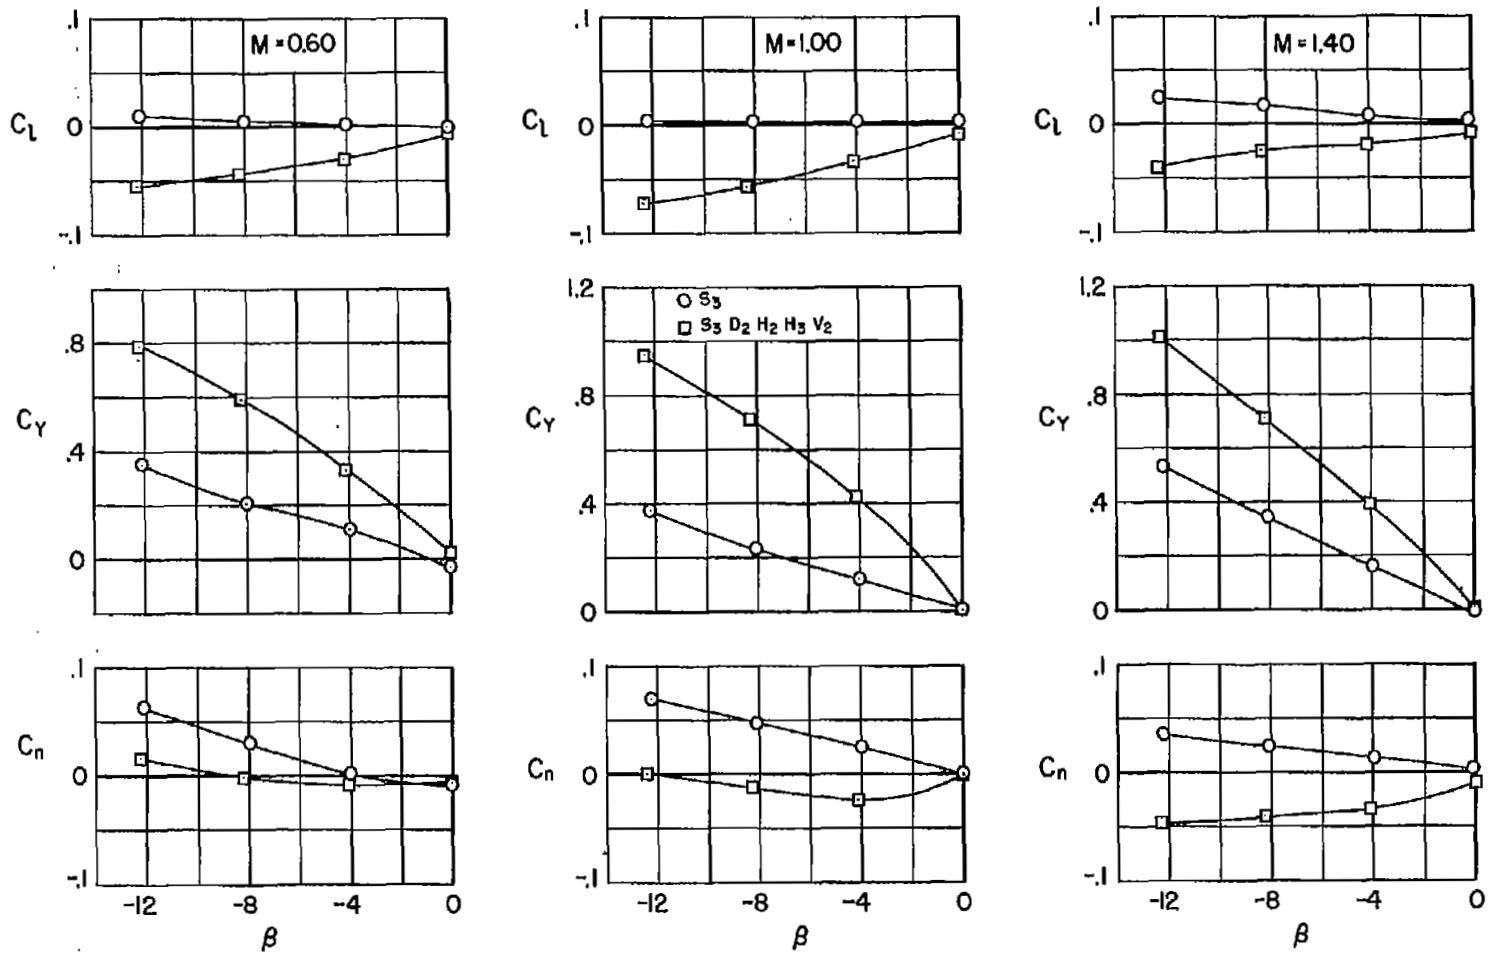

(a) Longitudinal characteristics at  $\beta = 0^\circ$ .

Figure 10.- Aerodynamic characteristics of the basic and modified downward ejected pilot-seat combinations.

(b) Lateral-directional characteristics at  $\alpha = 0^\circ$ .

Figure 10.- Concluded.
